Hence, if we wish to adopt the system in which t teeth shall always be at work, we must make $cse t = V^2 t$; (37) wherefore, to obtain the complete action of two teeth, we must use an inclination of 30. These contacts are all pragmatic, and, at first sight, the system would seem to include no others. However, that very circumstance which limits the rane of the working contacts calls into existence a set of supplementary ones. Thus, while the point of contact is passing along the side of the racktooth, the apex X is describing upon the blank disc a curve line which marks out the bottom of the tooth, and indicates the region of plerotic contact. And although the top and bottom of the tooth of the rack be contracted to a point, those of the wheels are not so. Hence, in addition to the two series of points which progress along the lines H G and F I, we have two other series describing F G and H I, with the velocity of the pitch lines, and separated from each other by intervals of $2ir$: one of each series comes alternately to the line of centres. The value of G F is clearly $ir \cdot \cot i1$, and therefore the number of intervals repeated along F G must be $\cot i2$; but the number of intervals repeated along F I is $cse iJ$, wherefore there is exactly...
